Theorie der Supraleitung, Herbstsemester 2018

Blatt 9

Abgabe und Besprechung: nach Vereinbarung

(1) **Cooper-pair box** (10 Punkte)
Consider the Cooper pair box Hamiltonian

$$\hat{H}_{\mathrm{CPB}} = 4E_C(\hat{N} - n_g)^2 - E_J \cos(\hat{\varphi})$$

where $n_g = q/(2e) = C_g V_g/(2e)$.

(a) Using the commutator $[e^{i\hat{\varphi}}, \hat{N}]_- = -e^{i\hat{\varphi}}$, write $\hat{H}_{\mathrm{CPB}}$ in the eigenbasis $\{|N\rangle\}_{N \in \mathbb{N}}$ of the charge operator.

(b) For $E_c \gg E_J$, sketch the energy spectrum as a function of n_g.

(c) Consider the point $n_g = N - 1/2$, for an integer $N \in \mathbb{N}$ and estimate the energy splitting of the two lowest eigenstates. **Hint:** Degenerate perturbation theory.

(d) Solve the Schrödinger equation of the Cooper-pair box

$$E\psi(N) = H\psi(N) = 4E_C \left(N - n_g\right)^2 \psi(N) - \frac{E_J}{2} \left[\psi(N-1) + \psi(N+1)\right]$$

numerically. Plot the eigenvalues as a function of n_g for different values of the ratio E_C/E_J and interpret your result. Compare with (b) and (c).

(2) **Zusatzaufgabe: Shapiro steps** (10 Punkte)
Assume an ideal Josephson junction that is voltage-biased with

$$V = V_0 + V_1 \cos \omega_1 t \,.$$

(a) Calculate the phase difference $\gamma(t)$ across the junction and write down the current $I = I_c \sin \gamma$.

(b) Use the addition theorem and the Fourier expansions of $\sin(z \sin(\theta))$ and $\cos(z \sin(\theta))$ (look them up!) to express the current I as a trigonometric series.

(c) Find the values of V_0 for which the current has a DC component.

(d) Since the integration constant in $\gamma(t)$ is arbitrary, the DC current corresponding to one of the "Shapiro" values in (c) can take different values. Find the width of the corresponding current region. These plateaus are called "Shapiro steps".
